

# Batch Name : PreCAT OM22 - Fast Track Batch  
# Module Name : Data Structures

---

Q. What is a data structure?

We want to store marks of 100 students

int m1, m2, m3, m4, ....., m100; //400 bytes

- we want to sort marks of 100 students in a descending order  
sorting

int marks[ 100 ]; //400 bytes

we want to store info of 100 students:

rollno: int  
name: char [ ]  
marks: float

struct employee emp[ 100 ];

- to learn data structure is not to learn any programming language, it is nothing but to learn **algorithms**.

Q. What is a Program?

- a program is a finite set of instructions written in any programming language given to the machine to do specific task.

Q. What is an algorithm?

- an algorithm is a finite set of instructions written in human understandable language like english, if followed, accomplishes given task.

- A Program is an implementation of an Algorithm

- An Algorithm is like a blueprint of a Program.

Algorithm ==> User / Pseudocode ==> Programmer User

Program ==> Machine

Q. What is a Pseudocode?

- an algorithm is a finite set of instructions written in human understandable language like english with some **programming constraints**, if followed, accomplishes given task, such algo is also called as pseudocode.

- pseudocode is a special form of an algo

**traversal on an array/to scan array ==>** to visit each array element sequentially from first element max till last element.

**Algorithm : to do sum of array elements:**

step-1: initially take sum as 0.

step-2: start traversal of an array and add each array element into the sum sequentially.

Step-3: return final sum

**Pseudocode/Special form of an algo: ==> Programmer User**

**Algorithm ArraySum( A, n)//A is an array having size n**

```
{
    sum = 0;
    for( index = 1 ; index <= n ; index++ ){
        sum += A[ index ];
    }

    return sum;
}
```

**Program: ==> Machine**

```
int array_sum( int arr[ ], int size ){
    int sum = 0;
    for( int index = 0 ; index < size ; index++ ){
        sum += arr[ index ];
    }

    return sum;
}
```

- An algorithm is a solution of a given problem

- algorithm = solution

- Problem: can we have multiple solutions for single problem

**Pune ==> Mumbai**

multiple paths exists between Pune & Mumbai

**efficient/optimized path ==>**

distance in km

cost required for

medium

traffic conditions

- **One problem may have multiple solutions**

**Searching:** to search given key element into a collection/list of elements

1. linear search
2. binary search

**Sorting:** to arrange data elements in a collection/list of elements either in an ascending order (or in a descending order).

1. bubble sort
  2. selection sort
  3. insertion sort
  4. merge sort
  5. quick sort
  6. heap sort
  7. radix sort
  8. shell sort
- etc....

- When we have multiple solutions/algo's for a single problem, we need to select an efficient solution/algo out of them, and to decide efficiency of an algo's we need to do their analysis.

- **analysis of an algo** is a work of calculating how much **time** i.e. computer time and **space** i.e. computer memory it needs to run to completion.

- there are two measures of analysis of an algo:

1. **time complexity** of an algo is the amount of time i.e. computer time it needs to run to completion.

2. **space complexity** of an algo is the amount of space i.e. computer memory it needs to run to completion.

### **Linear Search:**

**Best case : occurs if key is found at first position in only 1 comparison:  $O(1)$**

for size of an array = 10  $\Rightarrow$  no. of comparisons = 1

for size of an array = 20  $\Rightarrow$  no. of comparisons = 1

for size of an array = 30  $\Rightarrow$  no. of comparisons = 1

.

.

for size of an array = 50  $\Rightarrow$  no. of comparisons = 1

for size of an array = 100  $\Rightarrow$  no. of comparisons = 1

for size of an array =  $n \Rightarrow$  no. of comparisons = 1

**Worst case :** occurs if either key is found at last position or key is not found  $O(n)$ .

for size of an array = 10  $\Rightarrow$  no. of comparisons = 10

for size of an array = 20  $\Rightarrow$  no. of comparisons = 20

for size of an array = 30  $\Rightarrow$  no. of comparisons = 30

.

.

for size of an array = 50  $\Rightarrow$  no. of comparisons = 50

for size of an array = 100  $\Rightarrow$  no. of comparisons = 100

for size of an array =  $n \Rightarrow$  no. of comparisons =  $n$

**best case:** if an algo takes min amount of time to run to completion

**worst case:** if an algo takes max amount of time to run to completion

**average case:** if an algo takes neither min nor max amount of time to run to completion

for size of an array = 10  $\Rightarrow$  20 bytes/40 bytes  $\Rightarrow$  10 units

for size of an array = 20  $\Rightarrow$  40 bytes/80 bytes  $\Rightarrow$  20 units

for size of an array =  $n \Rightarrow$   $n$  units

Space Complexity =  $O(n)$ .

+ Rule: if running time of an algo is having any additive/subtractive/multiplicative/divisive constant then it can be neglected.  
e.g.

$O(n + 3) \Rightarrow O(n)$

$O(n - 4) \Rightarrow O(n)$

$O(n / 3) \Rightarrow O(n)$

$O(2 * n) \Rightarrow O(n)$

### + Binary Search:

by means of calculating mid pos big size array gets divided logically into two subarrays: left subarray & right subarray

for left subarray => value of left remains same, right = mid-1

for right subarray => value of right remains same, left = mid+1

if size of an array = 1000

iteration-1: [ 0 1 2 3 ..... 1000 ] => mid -> 1 comparison => 500  
[ 0.. 499 ] 500 [ 501 .... 1000 ]

iteration-2: [ 501 .... 1000 ] => mid = 750 => 1 comparison => 250  
[ 501..... 749 ] 750 [ 751 .... 1000 ]

iteration-3: [ 501 .... 750] 1 comparins => 125

after iteration-1: no. of cmp = 1,  $n/2$  =>  $T(n/2^1) + 1$

after iteration-2: no. of cmp = 2,  $n/4$  =>  $T(n/2^2) + 2$

after iteration-3: no. of cmp = 3,  $n/8$  =>  $T(n/2^3) + 3$

.

.

let us assume k no. of iterations takes

after iteration-k: no. of cmp = k,  $n/2^k$  =>  $T(n/2^k) + K$
